

European and Composite Stags

Analysis date: 1st December 2009

This sire summary is a list of sire breeding values calculated from a single analysis of information from herds located around New Zealand. This analysis enables the genetic performance of the sires used in these herds to be compared on the same basis, after differences in environment have been removed.

To appear on the list a stag must have a minimum of 5 progeny recorded, have a minimum accuracy for 12-month weight breeding value of 75%, and have progeny born in the last 2 years. This list contains European and composite stags. However, the breeding values are directly comparable with those of stags on the English list (providing both lists have the same analysis date recorded).

The information presented is for growth only, with the traits reported being weight at 12 months (W12) and mature weight of hinds (MWT). Both breeding values (BV) and accuracy of each breeding value (acc%) are reported. Number of progeny are reported as "number born in the last 2 years/total number of progeny" where the two numbers differ. The list is in alphabetical order, with stags falling in the top 10 percentile band for 12-month weight having their breeding value highlighted in bold type.

DISCLAIMER: While every endeavour has been made to ensure the accuracy of information in this report, SIL and AgResearch expressly disclaims any and all liabilities that may arise from the use of the information.
